Two basic types of processes affecting the long-term safe containment and isolation of radioactive waste in deep geological repositories are examined; (1) delay-and-decay processes and (2) concentration-attenuation processes. The robustness of different types of isolation processes, based on their effectiveness and reliability, are discussed.

Repositories for the disposal of radioactive waste generally rely on a multi-barrier system to isolate the waste from the biosphere. This multi-barrier system typically comprises the natural geological barrier provided by the repository host rock and its surroundings and an engineered barrier system (EBS).

Engineered Barrier Systems and the Safety of Deep ...

A deep geological repository is a way of storing toxic or radioactive waste within a stable geologic environment (typically 200-1000 m deep). It entails a combination of waste form, waste package, engineered seals and geology that is suited to provide a high level of long-term isolation and containment without future maintenance.

A geological repository and safety case relies on multiple fail-safe mechanisms underpinned by man-made barriers (active controls) and natural barriers (passive controls). Geological repositories rely mostly on passive controls which do not require ongoing monitoring as they can be quantified as being passively safe through geological time.
